R Data Structures

There are a number of data structures in R such as **vectors**, **lists**, **matricies** and **arrays** but the premier data structure in R is known as the **data.frame**. This structure can be described as follows:

- A data frame is a special type of list that contains data in a format that allows for easier manipulation, reshaping, and open-ended analysis
- Data frames are tightly coupled collections of variables. It is one of the more important constructs you will encounter when using R so learn all you can about it
- A data frame is an analogue to the Excel spreadsheet but is much more flexible for storing, manipulating, and analyzing data
- Data frames can be constructed from existing vectors, lists, or matrices. Many times they are created by reading in comma delimited files, (CSV files), using the read.table command

Once you become accustomed to working with data frames, R becomes so much easier to use. In fact, it could be well argued the UNTIL you wrap your head around the data frame concept then you cannot be productive in R. This is mostly true, in my experience.

1.1 A Reference Data Frame

We will use a well-known data frame, at least in R circles, called **mtcars** which is part of any default installation of R. It is a simple data set relating to, well, automobiles.

The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects

Figure 1.1:

```
of automobile design and performance for 32 automobiles
(1973-74 models).
A data frame with 32 observations on 11 (numeric)
variables.
[, 1]
        mpg Miles/(US) gallon
[, 2]
        cyl Number of cylinders
[, 3]
                Displacement (cu.in.)
[, 4]
        hp Gross horsepower
[, 5]
                Rear axle ratio
        drat
[, 6]
        wt Weight (1000 lbs)
[, 7]
                1/4 mile time
        qsec
        vs Engine (0 = V-shaped, 1 = straight)
[, 8]
[, 9]
            Transmission (0 = automatic, 1 = manual)
[,10]
        gear
                Number of forward gears
[,11]
                Number of carburetors
        carb
```

1.2 Relation to dplyr

What you will discover is that the **dplyr** package, which is part of the much larger **tidyverse** package set, extends upon the idea of the basic R data frame in a way that some feel is superior. It depends on your point of view though the **tidyverse** has a lot of consistency in it which makes it **very** useful. However you will inevitably encounter older R code which does not use it. This is why you have to have some basic understanding of the basic data frame concept.

Data Frame Details

R comes with with a variety of built-in data sets that are very useful for getting used to data sets and how to manipulate them.

AirPassengers	Monthly Airline	Passenger Numbers	1949-1960
---------------	-----------------	-------------------	-----------

BJsales Sales Data with Leading Indicator

BOD Biochemical Oxygen Demand

CO2 Carbon Dioxide Uptake in Grass Plants

ChickWeight Weight versus age of chicks on different diets

DNase Elisa assay of DNase

Formaldehyde Determination of Formaldehyde

LakeHuron Level of Lake Huron 1875-1972

Loblolly Growth of Loblolly pine trees

Nile Flow of the River Nile
Orange Growth of Orange Trees
OrchardSprays Potency of Orchard Sprays

PlantGrowth Results from an Experiment on Plant Growth
Puromycin Reaction Velocity of an Enzymatic Reaction

Theoph Pharmacokinetics of Theophylline

2.1 An Example

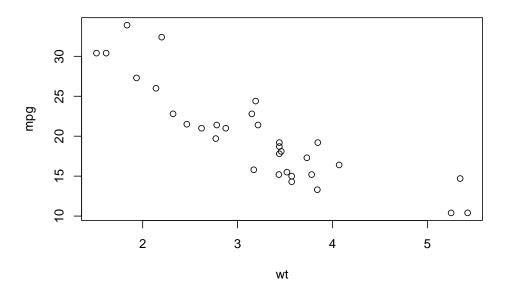

Data frames look like an Excel Spreadsheet. The rows are observations and the columns are variables or "features" that represent some measurement or character-based description of a given observation. When viewed from the row point of view, the data can be heterogenous. When viewed as a column, the data is homogenous.

```
data(mtcars)
mtcars
```

```

                                                                         5
## Volvo 142E
                         21.4
                                4 121.0 109 4.11 2.780 18.60
                                                                              2
```

We can do this with this data such as make plots or create models:

```
plot(mpg ~ wt, data=mtcars)
```

Let's create a regression model. It doesn't take long to realize that most functions in R will use a data frame as input. This means that you will spend a lot of time working with data frames to get them into shape for use with modeling and visualization tools. In fact you will spend most of your time **importing**, **transforming**, and cleaning.

```
(mylm <- lm(mpg ~ ., data = mtcars))</pre>
```

```
##
## Call:
## lm(formula = mpg ~ ., data = mtcars)
##
## Coefficients:
   (Intercept)
                                                                   drat
                          cyl
                                       disp
                                                       hp
      12.30337
                     -0.11144
                                    0.01334
                                                 -0.02148
                                                                0.78711
##

             wt
                         qsec
                                         vs
                                                       am
##
      -3.71530
                     0.82104
                                    0.31776
                                                  2.52023
                                                                0.65541
##
          carb
##
      -0.19942
```

There are some useful functions that help you understand the structure of a data frame. One of the most important ones is called the **str()** function which is short hand for **structure**.

2.2 Structure

```
str(mtcars)
## 'data.frame':
                    32 obs. of 11 variables:
    $ mpg : num 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
    $ cyl : num 6 6 4 6 8 6 8 4 4 6 ...
##
   $ disp: num 160 160 108 258 360 ...
                110 110 93 110 175 105 245 62 95 123 ...
   $ hp : num
##
    $ drat: num 3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...
##
    $ wt : num 2.62 2.88 2.32 3.21 3.44 ...
##
    $ qsec: num 16.5 17 18.6 19.4 17 ...
##
   $ vs
         : num
               0 0 1 1 0 1 0 1 1 1 ...
         : num 1 1 1 0 0 0 0 0 0 0 ...
##
   $ am
                4 4 4 3 3 3 3 4 4 4 ...
    $ gear: num
   $ carb: num 4 4 1 1 2 1 4 2 2 4 ...
```

This gives you some idea about the number of rows and columns of the data frame along with a description of the variable types and their values. I use this function frequently. Other functions that will help you include the following.

2.3 Meta Information

```
# how many rows
nrow(mtcars)

## [1] 32

# how many columns
ncol(mtcars)

## [1] 11

# Column names
names(mtcars)

## [1] "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs" "am" "gear"
## [11] "carb"
```

2.4 Printing

Some data frames, such as mtcars, don't have many rows but others might have hundreds, thousands or even more than that! Imagine trying to view one of

those data frames. It is for this reason that the **head()** and **tail()** functions exist

```
head(mtcars,5) # First 5 rows
##
                      mpg cyl disp hp drat
                                                wt qsec vs am gear carb
## Mazda RX4
                                160 110 3.90 2.620 16.46
                                                          0
                     21.0
## Mazda RX4 Wag

```

2.5 Accessing Rows And Columns

There are various ways to select, remove, or exclude rows and columns of a data frame. We use the **bracket** notation to do this. This is very powerful. Keep in mind that data frames have rows and columns so it would make sense that you need a way to specify what rows and columns you want to access.

```
mtcars[1,]
               # First row, all columns
##
             mpg cyl disp hp drat
                                     wt qsec vs am gear carb
## Mazda RX4 21
                   6 160 110 3.9 2.62 16.46
mtcars[1:3,]
             # First three rows, all columns
##
                  mpg cyl disp hp drat
                                            wt
                                               qsec vs am gear carb
## Mazda RX4
                 21.0
                           160 110 3.90 2.620 16.46
                                                      0
                                                         1

2.6 Interrogating

Many times you will wish to find rows that satisfy certain conditions. For example, what rows have an mpg > 11 and at wt < 2.0? We use the bracket notation to help us. We can pass logical conditions into the brackets. Note the following:

```
mtcars$mpg > 11 & mtcars$wt < 2.0
```

```
## [1] FALSE FALSE
```

There are 32 elements in this logical vector each with a value of either TRUE or FALSE. When passed into the row index of the bracket notation, it will print that row if the corresponding value is TRUE. If FALSE, the row will not be printed.

```
mtcars[mtcars$mpg > 11 & mtcars$wt < 2.0,]</pre>
```

```
mpg cyl disp
                                hp drat
                                            wt
                                                qsec vs am gear carb
## Honda Civic

2.7 Missing values

This is big deal. Most "real" data has rows that do not contain values for all columns. This is the so called "missing value" problem. Here is an example. The following code will read in a version of the mtcars data frame that has

some missing values:

url <- "https://raw.githubusercontent.com/steviep42/utilities/master/data/mtcars_na.csv"
(mtcars_na <- read.csv(url, stringsAsFactors = FALSE))</pre>

```

                                            1
```

If you look, you can see the missing values "NA" present in certain columns. This is R's way of indicating what is missing. There are functions that can help you find these. This is important because, for example, if you wanted to find the average value of a column, say the **wt** column then there will be a problem as it contains a missing value:

```
mean(mtcars_na$wt)
```

[1] NA

TRUE

TRUE

mean(mtcars\$wt, na.rm=TRUE) ## [1] 3.21725 A more general approach would involve the following functions. complete.cases(mtcars_na) ## [1] TRUE FALSE TRUE TRUE FALSE FALSE TRUE TRUE TRUE TRUE ## [12] FALSE TRUE FALSE FALSE TRUE TRUE TRUE TRUE TRUE TRUE

We have to tell the function to remove missing values from consideration.

[1] 24

```
# How many rows in the df do contain at least one NA ?
sum(!complete.cases(mtcars_na))
```

[1] 8

How would we find those rows and print them?

```
mtcars_na[complete.cases(mtcars_na),]
```

```

## 32 21.4
             4 121.0 109 4.11 2.780 18.60 1 1
                                                         2
```

2.8 Continuous vs Factors

One **recipe** that I use frequently is given below. This tells me how many unque values are assumed by each column which then helps to identify continuous quantities and categories. If a column assumes only a small number of unique values then perhaps it should be classified as a factor. Don't let the code here scare you. If you are new to R and don't yet understand what is going on then just use this as a "recipe" for now.

```
sapply(mtcars, function(x) length(unique(x)))
##
    mpg
         cyl disp
                     hp drat
                                 wt qsec
                                            vs
                                                 am gear carb
##
     25
            3
                27
                      22
                           22
                                 29
                                      30
                                             2
                                                  2
                                                        3
```

So it looks to me, for example, that **cyl**, **vs**, **am**, **gear**, **and carb** are actually categories rather than measured quantities. If you look at the help page for mtcars you will see that **am** is a 0 or 1 which corresponds to, respectively, a car with an automatic transmission (0) or a manual transmission (1). If you use the **summarize** function it will treat this variable as a numeric, continuous quantity.

Is it actually possible to have a transmission value of 0.4062?

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.0000 0.0000 0.0000 0.4062 1.0000 1.0000
```

I might then use some code to transform this into factors so that when they are used with various modeling functions they will be recognized as such. For example, if we summarize the data frame right now, we will see the following

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.0000 0.0000 0.0000 0.4062 1.0000 1.0000
```

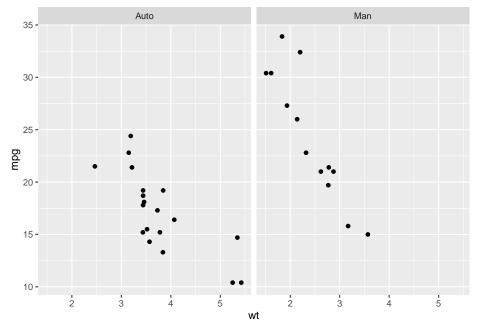

Let's turn am into a factor

Now the summary will make more sense. This is also useful because graphics packages such as ggplot2 will know how to handle factors.

```
summary(mtcars$am)

## Auto Man
## 19 13
```

2.9 Sorting data

Sorting rows in a data fram is a common activity. However, in Base R this is called "ordering" because of the function used to "order" the data. Let's say we want to sort or "order" the mtcars data frame such that the row with the lowest mpg value is listed first and the row with the highest mpg value is listed last. First, look at the **order** function's output. What are those numbers?

```
order(mtcars$mpg)
```

```
## [1] 15 16 24 7 17 31 14 23 22 29 12 13 11 6 5 10 25 30 1 2 4 32 21 ## [24] 3 9 8 27 26 19 28 18 20
```

Oh, so they are row numbers corresponding to rows in mtcars. Row 15 has the car with the lowest mpg. Row 16 corresponds to the car with the next lowest mpg and so on. So we can use this information to order our dataframe accordingly:

```
mtcars[order(mtcars$mpg),]
```

Literature

Here is a review of existing methods.

Methods

We describe our methods in this chapter.

Applications

Some significant applications are demonstrated in this chapter.

- 5.1 Example one
- 5.2 Example two

Final Words

We have finished a nice book.
