Chapter 1

R Data Structures

There are a number of data structures in R such as **vectors**, **lists** qnd **matrices**. The **vector** structure winds up being helpful in understanding how to work with data frames.

1.1 Vectors

It is a container for a series of related data of the same type: height measurements of students, whether a group of people smoke or not, their blood pressure. The only rule here is that a vector can contain only one data type at a time.

```
names <- c("P1","P2","P3","P4","P5")

temp <- c(98.2,101.3,97.2,100.2,98.5)

pulse <- c(66,72,83,85,90)

gender <- c("M","F","M","M","F")
```

To access elements, or ranges of elements, within a vector involves using the "bracket" notation:

```
# Get the first element of temp
temp[1]

## [1] 98.2

# Get elements 3,4, and 5 from pulse
pulse[3:5]

## [1] 83 85 90
```

We can also use logical expressions to find elements that satisfy some condition. This is a very powerful capability in R.

```
temp < 98
```

```
## [1] FALSE FALSE TRUE FALSE FALSE
```

Whoa. What was that? Well we get back a T/F logical vector that tells us what elements satisfy the specified condition. We can then use this info to get the elements of interest.

```
temp[temp < 98]
```

```
## [1] 97.2
```

Working with individual vectors is fine but a more general way of working with them is in data frames which provides more fleibility:

```
(my_df <- data.frame(names,temp,pulse,gender))</pre>
```

```
##
            temp pulse gender
     names
## 1
        P1 98.2
                     66
                             Μ
## 2
                             F
        P2 101.3
                     72
## 3
        P3 97.2
                     83
                             Μ
## 4
        P4 100.2
                     85
                             М
                             F
## 5
        P5 98.5
                     90
```

Looking at each column, we see that they are the vectors we were just working with. If we need to access them from the data frame it's easy.

```
# Get the temp column
my_df$temp
```

```
## [1] 98.2 101.3 97.2 100.2 98.5

# What's the mean of the temp column
mean(my_df$temp)
```

```
## [1] 99.08
```

1.2 Data Frames

But we are getting ahead of ourselves. Just know that the **premier data structure** in R is the **data.frame**. This structure can be described as follows:

- A data frame is a special type of list that contains data in a format that allows for easier manipulation, reshaping, and open-ended analysis
- Data frames are tightly coupled collections of variables. It is one of the more important constructs you will encounter when using R so learn all you can about it
- A data frame is an analogue to the Excel spreadsheet but is much more flexible for storing, manipulating, and analyzing data
- Data frames can be constructed from existing vectors, lists, or matrices. Many times they are created by reading in comma delimited files, (CSV files), using the read.table command

Once you become accustomed to working with data frames, R becomes so much easier to use. In fact, it could be well argued the UNTIL you wrap your head around the data frame concept then you cannot be productive in R. This is mostly true, in my experience.

R comes with with a variety of built-in data sets that are very useful for getting used to data sets and how to manipulate them.

AirPassengers	Monthly Airline Passenger Numbers 1949-1960
BJsales	Sales Data with Leading Indicator
BOD	Biochemical Oxygen Demand
C02	Carbon Dioxide Uptake in Grass Plants
ChickWeight	Weight versus age of chicks on different diets
DNase	Elisa assay of DNase
Formaldehyde	Determination of Formaldehyde
HairEyeColor	Hair and Eye Color of Statistics Students
Harman23.cor	Harman Example 2.3

Harman74.cor	Harman Example 7.4
Indometh	Pharmacokinetics of Indomethacin
InsectSprays	Effectiveness of Insect Sprays
JohnsonJohnson	Quarterly Earnings per Johnson & Johnson Share
LakeHuron	Level of Lake Huron 1875-1972
LifeCycleSavings	Intercountry Life-Cycle Savings Data
Loblolly	Growth of Loblolly pine trees
Nile	Flow of the River Nile
Orange	Growth of Orange Trees
OrchardSprays	Potency of Orchard Sprays
PlantGrowth	Results from an Experiment on Plant Growth
Puromycin	Reaction Velocity of an Enzymatic Reaction
Theoph	Pharmacokinetics of Theophylline

1.3 A Reference Data Frame

We will use a well-known data frame, at least in R circles, called **mtcars** which is part of any default installation of R. It is a simple data set relating to, well, automobiles. This data frame has the distinction of being the most (ab)used data frame in R education.

```
The data was extracted from the 1974 Motor Trend US
magazine, and comprises fuel consumption and 10 aspects
of automobile design and performance for 32 automobiles
(1973-74 \text{ models}).
A data frame with 32 observations on 11 (numeric)
variables.
[, 1]
        mpg Miles/(US) gallon
[, 2]
        cyl Number of cylinders
[, 3]
                Displacement (cu.in.)
        disp
[, 4]
        hp Gross horsepower
[, 5]
                Rear axle ratio
        drat
[, 6]
        wt Weight (1000 lbs)
[, 7]
                1/4 mile time
        qsec
[, 8]
        vs Engine (0 = V-shaped, 1 = straight)
        am Transmission (0 = automatic, 1 = manual)
[, 9]
[,10]
                Number of forward gears
        gear
                Number of carburetors
[,11]
        carb
```

1.4 Relation to dplyr

What you will discover is that the **dplyr** package, which itself is part of the much larger **tidyverse** package set, extends upon the idea of the basic R data frame in a way that some feel is superior. It depends on your point of view though the **tidyverse** has a lot of what I call a philosophic consistency in it which makes it **very** useful once you get some concepts in mind.

While you could start exclusively with **dplyr** and the **tidyverse** the world is still full of older code. Plus, many of the advantages of **dplyr** only become quite apparent when compared to the "older way" of doing things. So my recommendation is to know how to deal with data frames in base R while also spending time to learn the **dplyr** way of doing things.

Chapter 2

Digging In

Data frames look like an Excel Spreadsheet. The rows are observations and the columns are variables or "features" that represent some measurement or character-based description of a given observation. When viewed from the row point of view, the data can be heterogenous. When viewed as a column, the data is homogenous.

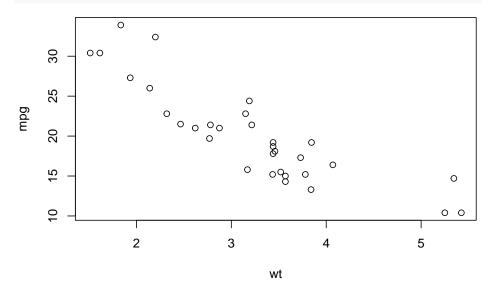

```
data(mtcars)
mtcars
```

```
##
                                 disp hp drat
                                                    wt
                                                       qsec vs am gear carb
## Mazda RX4
                       21.0
                               6 160.0 110 3.90 2.620 16.46
## Mazda RX4 Wag
                       21.0
                               6 160.0 110 3.90 2.875 17.02
                                                                            4
## Datsun 710
                       22.8
                               4 108.0 93 3.85 2.320 18.61
                                                                            1
## Hornet 4 Drive
                       21.4
                               6 258.0 110 3.08 3.215 19.44
                                                                            1
## Hornet Sportabout
                       18.7
                               8 360.0 175 3.15 3.440 17.02
                                                                            2
## Valiant
                       18.1
                               6 225.0 105 2.76 3.460 20.22
                                                                            1
## Duster 360
                       14.3
                               8 360.0 245 3.21 3.570 15.84
                                                                      3
                                                                            4
## Merc 240D
                       24.4
                               4 146.7
                                        62 3.69 3.190 20.00
                                                                            2
                               4 140.8
## Merc 230
                       22.8

                                                                       5
                                                                             6
                                                                  1
## Maserati Bora
                        15.0
                               8 301.0 335 3.54 3.570 14.60
                                                                       5
                                                                             8
## Volvo 142E
                        21.4
                               4 121.0 109 4.11 2.780 18.60
                                                                             2
```

We can do this with this data such as make plots or create models:

```
plot(mpg ~ wt, data=mtcars)
```

Let's create a regression model. It doesn't take long to realize that most functions in R will use a data frame as input. This means that you will spend a lot of time working with data frames to get them into shape for use with modeling and visualization tools. In fact you will spend most of your time **importing**, **transforming**, and cleaning.

```
(mylm <- lm(mpg ~ ., data = mtcars))

##
## Call:
## lm(formula = mpg ~ ., data = mtcars)
##
## Coefficients:</pre>
```

##	(Intercept)	cyl	disp	hp	drat
##	12.30337	-0.11144	0.01334	-0.02148	0.78711
##	wt	qsec	vs	am	gear
##	-3.71530	0.82104	0.31776	2.52023	0.65541
##	carb				
##	-0.19942				

There are some useful functions that help you understand the structure of a data frame. One of the most important ones is called the **str()** function which is short hand for **structure**.

2.1 Structure

```
str(mtcars)
## 'data.frame':
                    32 obs. of 11 variables:
                 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
   $ mpg : num
   $ cyl : num
                 6 6 4 6 8 6 8 4 4 6 ...
   $ disp: num
                 160 160 108 258 360 ...
   $ hp
         : num
                 110 110 93 110 175 105 245 62 95 123 ...
   $ drat: num
                 3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...
                 2.62 2.88 2.32 3.21 3.44 ...
   $ wt : num
    $ qsec: num
                 16.5 17 18.6 19.4 17 ...
                 0 0 1 1 0 1 0 1 1 1 ...
##
   $ vs
         : num
                 1 1 1 0 0 0 0 0 0 0 ...
         : num
   $ gear: num
                 4 4 4 3 3 3 3 4 4 4 ...
   $ carb: num
                4 4 1 1 2 1 4 2 2 4 ...
```

This gives you some idea about the number of rows and columns of the data frame along with a description of the variable types and their values. I use this function frequently. Other functions that will help you include the following.

2.2 Meta Information

[1] 11

```
# how many rows
nrow(mtcars)

## [1] 32

# how many columns
ncol(mtcars)
```

```
# Column names
names(mtcars)

## [1] "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs" "am" "gear"
## [11] "carb"
```

2.3 Printing

Some data frames, such as mtcars, don't have many rows but others might have hundreds, thousands or even more than that! Imagine trying to view one of those data frames. It is for this reason that the **head()** and **tail()** functions exist.

```
head(mtcars,5) # First 5 rows
##
                      mpg cyl disp hp drat
                                               wt qsec vs am gear carb
## Mazda RX4
                     21.0
                            6 160 110 3.90 2.620 16.46
## Mazda RX4 Wag
                     21.0
                            6
                               160 110 3.90 2.875 17.02
                                                                       4
## Datsun 710
                     22.8
                                   93 3.85 2.320 18.61
## Hornet 4 Drive
                     21.4
                               258 110 3.08 3.215 19.44
                                                                  3
                                                                       1
                            6
## Hornet Sportabout 18.7
                               360 175 3.15 3.440 17.02
tail(mtcars,3) # Last 3 rows
                  mpg cyl disp hp drat
                                          wt qsec vs am gear carb
## Ferrari Dino
                 19.7
                        6
                           145 175 3.62 2.77 15.5
## Maserati Bora 15.0
                        8 301 335 3.54 3.57 14.6
                                                                 8
## Volvo 142E
                 21.4
                          121 109 4.11 2.78 18.6
                                                                 2
```

2.4 Accessing Rows And Columns

There are various ways to select, remove, or exclude rows and columns of a data frame. We use the **bracket** notation to do this. This is very powerful. Keep in mind that data frames have rows and columns so it would make sense that you need a way to specify what rows and columns you want to access.

```
mtcars[1,]
              # First row, all columns
##
            mpg cyl disp hp drat
                                   wt qsec vs am gear carb
## Mazda RX4 21
                6 160 110 3.9 2.62 16.46
mtcars[1:3,]
              # First three rows, all columns
                 mpg cyl disp hp drat
                                         wt qsec vs am gear carb
## Mazda RX4
                21.0
                         160 110 3.90 2.620 16.46
## Mazda RX4 Wag 21.0
                      6 160 110 3.90 2.875 17.02 0
```

```
## Datsun 710
                22.8
                       4 108 93 3.85 2.320 18.61 1 1
# All rows, and first 4 columns
mtcars[,1:4]
##
                      mpg cyl disp hp
## Mazda RX4
                      21.0
                            6 160.0 110

2.5 Interrogation

Many times you will wish to find rows that satisfy certain conditions. For example, what rows have an mpg > 11 and at wt < 2.0? We use the bracket notation to help us. We can pass logical conditions into the brackets. Note the following:

```
mtcars$mpg > 11 & mtcars$wt < 2.0
```

```
## [1] FALSE FALSE
```

There are 32 elements in this logical vector each with a value of either TRUE or FALSE. When passed into the row index of the bracket notation, it will print that row if the corresponding value is TRUE. If FALSE, the row will not be printed.

```
mtcars[mtcars$mpg > 11 & mtcars$wt < 2.0,]</pre>
##
                    mpg cyl disp
                                  hp drat
                                              wt
                                                 qsec vs am gear carb
## Honda Civic
                   30.4
                          4 75.7
                                  52 4.93 1.615 18.52
                                                         1
                                                                 4
                                                                      2
## Toyota Corolla 33.9
                                  65 4.22 1.835 19.90
                                                                 4
                                                                      1
                          4 71.1
                                                         1
                                                            1
## Fiat X1-9
                   27.3
                          4 79.0 66 4.08 1.935 18.90

```

2.6 Missing values

This is big deal. Most "real" data has rows that do not contain values for all columns. This is the so called "missing value" problem. Here is an example. The following code will read in a version of the mtcars data frame that has some missing values:

url <- "https://raw.githubusercontent.com/steviep42/utilities/master/data/mtcars_na.cs
(mtcars_na <- read.csv(url, stringsAsFactors = FALSE))</pre>

```

```

If you look, you can see the missing values "NA" present in certain columns. This is R's way of indicating what is missing. There are functions that can help you find these. This is important because, for example, if you wanted to find the average value of a column, say the **wt** column then there will be a problem as it contains a missing value:

```
mean(mtcars_na$wt)
```

```
## [1] NA
```

We have to tell the function to remove missing values from consideration.

```
mean(mtcars$wt, na.rm=TRUE)
```

```
## [1] 3.21725
```

A more general approach would involve the following functions.

```
complete.cases(mtcars_na)
```

```
##
    [1]
         TRUE FALSE
                      TRUE
                            TRUE
                                   TRUE
                                         TRUE
                                               TRUE
                                                      TRUE FALSE FALSE
                                                                         TRUE
## [12] FALSE
               TRUE
                      TRUE
                            TRUE
                                   TRUE
                                         TRUE
                                               TRUE FALSE FALSE
                                                                  TRUE
                                                                         TRUE
## [23] FALSE
               TRUE
                     TRUE
                            TRUE
                                  TRUE FALSE
                                               TRUE
                                                      TRUE
                                                            TRUE
                                                                  TRUE
```

```
# How many rows in the df do not contain any NAs ?
sum(complete.cases(mtcars_na))
```

```
## [1] 24
```

```
# How many rows in the df do contain at least one NA ?
sum(!complete.cases(mtcars_na))
```

[1] 8

How would we find those rows and print them?

```
mtcars_na[complete.cases(mtcars_na),]
```

```

                                                      5
                                                           6
## 31 15.0
             8 301.0 335 3.54 3.570 14.60
                                                      5
                                                           8
## 32 21.4
             4 121.0 109 4.11 2.780 18.60
                                                      4
                                                           2
```

2.7 Continuous vs Factors

One **recipe** that I use frequently is given below. This tells me how many unque values are assumed by each column which then helps to identify continuous quantities and categories. If a column assumes only a small number of unique values then perhaps it should be classified as a factor. Don't let the code here scare you. If you are new to R and don't yet understand what is going on then just use this as a "recipe" for now.

```
sapply(mtcars, function(x) length(unique(x)))
## mpg cyl disp hp drat wt qsec vs am gear carb
## 25 3 27 22 22 29 30 2 2 3 6
```

So it looks to me, for example, that **cyl**, **vs**, **am**, **gear**, **and carb** are actually categories rather than measured quantities. If you look at the help page for mtcars you will see that **am** is a 0 or 1 which corresponds to, respectively, a car with an automatic transmission (0) or a manual transmission (1). If you use the **summarize** function it will treat this variable as a numeric, continuous quantity.

Is it actually possible to have a transmission value of 0.4062?

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.0000 0.0000 0.0000 0.4062 1.0000 1.0000
```

I might then use some code to transform this into factors so that when they are used with various modeling functions they will be recognized as such. For example, if we summarize the data frame right now, we will see the following

```
summary(mtcars$am)
```

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
```

```
## 0.0000 0.0000 0.0000 0.4062 1.0000 1.0000
```

Let's turn am into a factor

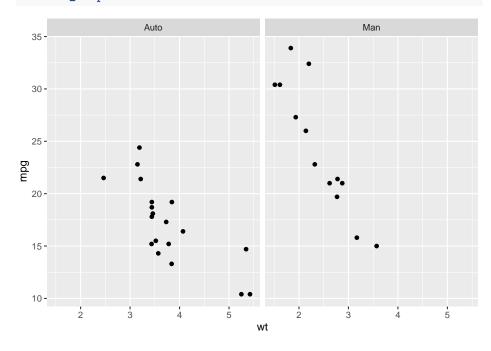

Now the summary will make more sense. This is also useful because graphics packages such as ggplot2 will know how to handle factors.

```
summary(mtcars$am)

## Auto Man

## 19 13

ggplot(mtcars,aes(x=wt,y=mpg)) +
    geom_point() +
    facet_wrap(~am)
```

2.8 Sorting data

Sorting rows in a data fram is a common activity. However, in Base R this is called "ordering" because of the function used to "order" the data. Let's say we want to sort or "order" the mtcars data frame such that the row with the

lowest mpg value is listed first and the row with the highest mpg value is listed last. First, look at the **order** function's output. What are those numbers?

order(mtcars\$mpg)

```
## [1] 15 16 24  7 17 31 14 23 22 29 12 13 11  6  5 10 25 30  1  2  4 32 21 ## [24]  3  9  8 27 26 19 28 18 20
```

Oh, so they are row numbers corresponding to rows in mtcars. Row 15 has the car with the lowest mpg. Row 16 corresponds to the car with the next lowest mpg and so on. So we can use this information to order our dataframe accordingly:

mtcars[order(mtcars\$mpg),]

```
##
                         mpg cyl
                                  disp hp drat
                                                    wt
                                                        qsec vs
                                                                   am gear carb
## Cadillac Fleetwood
                       10.4

To invert the sense of the order use the **rev** function. We'll also use the head function to list only the first 5 rows of the result. Note that in base R, using composite functions is welcomed although you will find out that this is not a value in the tidyverse. For math people, using a composite function is natural which, in large part, is why R embraced that approach early on.

```
head(mtcars[rev(order(mtcars$mpg)),])
```

```

2.9 Reading CSV Files

Many times data will be read in from a comma delimited file exported from Excel. These are known as Comma Separated Value files - generally abbreviated as CSV. The file can be read from a local drive or even from the Web as long as you know the URL associated with the file. In this example, there is a file on the Internet relating to some testing data involving students and various subjects.

```
url <- "https://raw.githubusercontent.com/pittardsp/bios545r_spring_2018/master/SUPPOR'
data1 <- read.csv(url,header=T,sep=",")
head(data1)</pre>
```

```

Chapter 3

The tidyverse

The **dplyr** package is part of the larger **tidyverse** package set which has expanded considerably in recent years and continues to grow in size and utility such that many people never learn the "older way" of doing things in R. But we've already been through that in the previous section. The tidyverse has the following packages. The descriptions have been lifted from the tidyverse home page.

ggplot2 - ggplot2 is a system for declaratively creating graphics, based on The Grammar of Graphics. You provide the data, tell ggplot2 how to map variables to aesthetics, what graphical primitives to use, and it takes care of the details.

dplyr - dplyr provides a grammar of data manipulation, providing a consistent set of verbs that solve the most common data manipulation challenges.

tidyr - tidyr provides a set of functions that help you get to tidy data. Tidy data is data with a consistent form: in brief, every variable goes in a column, and every column is a variable.

readr - readr provides a fast and friendly way to read rectangular data (like csv, tsv, and fwf). It is designed to flexibly parse many types of data found in the wild, while still cleanly failing when data unexpectedly changes.

tibble - tibble is a modern re-imagining of the data frame, keeping what time has proven to be effective, and throwing out what it has not. Tibbles are data frames that are lazy and surly: they do less and complain more forcing you to confront problems earlier, typically leading to cleaner, more expressive code.

stringr - stringr provides a cohesive set of functions designed to make working with strings as easy as possible. It is built on top of stringi, which uses the ICU C library to provide fast, correct implementations of common string manipulations.

lubdriate - Date-time data can be frustrating to work with in R. R commands for date-times are generally unintuitive and change depending on the type of date-time object being used. Moreover, the methods we use with date-times must be robust to time zones, leap days, daylight savings times, and other time related quirks. Lubridate makes it easier to do the things R does with date-times and possible to do the things R does not.

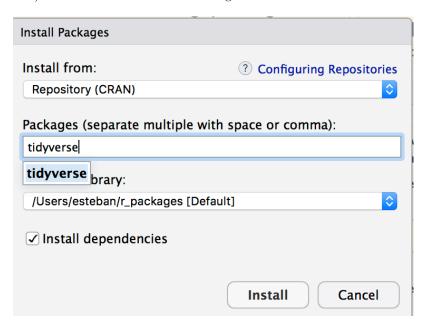

3.1 Installing

You will probably use a number of functions from several of these packages so it's best to go ahead and install the entire **tidyverse** in one go. To install it, do one of the following:

1) At the R Console from within RStudio, type:

install.packages("tidyverse")

2) Use the Tools -> Install Packages menu item in RStudio:

After you have installed the package you may load it by doing:

suppressMessages(library(tidyverse))

Note that the **cheatsheet** for **dplyr** can be found here

Data Transformation with dplyr:: cheat sheet

3.2 dplyr Basics

dplyr is a grammar of data manipulation, providing a consistent set of verbs that help you solve the most common data manipulation challenges. In fact if you were paying attention during the opening section on data frames you will have noticed that most of the activities we performed related to the following activires. In dplyr-speak there are the **verbs** that help us get work done.

```
mutate() - adds new variables that are functions of existing variables
select() - picks variables based on their names.
filter() - picks cases based on their values.
summarise() - reduces multiple values down to a single summary.
arrange() - changes the ordering of the rows.
```

3.3 First Steps

Note that this material references "Becoming a data ninja with dplyr" as well as this dplyr tutorial

We'll go back to the basics here by using a very small data frame which will make it clear how the various **dplyr** verbs actually work:

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

3.3.1 filter()

The **filter()** function allows us to sift through the data frame to find rows that satisfy some logical condition. (With the older approach we would be using the bracket notation). The following example allows is to find only the observations relating to a declared gender of **female**.

```
## id gender age
## 1 3 FEMALE 60
## 2 5 FEMALE 68

# Given this data frame, the following is equivalent

filter(df, gender != "MALE")

## id gender age
## 1 3 FEMALE 60
## 2 5 FEMALE 68
```

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

ID	GENDER	AGE
3	FEMALE	60
5	FEMALE	68

So, now find only the **ids** that relate to rows 1,3, or 5. This is a highly specialized search but it is helpful to show that you can use a wide variety of logical constructs.

```
filter(df, id %in% c(1,3,5))
```

```
## 1 id gender age
## 1 1 1 MALE 70
## 2 3 FEMALE 60
## 3 5 FEMALE 68
```

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

ID	GENDER	AGE
1	MALE	70
3	FEMALE	60
5	FEMALE	68

3.3.2 mutate()

Mutate is used to add or remove columns in a data frame. Let's create a new column in the data frame that contains the mean value of the age column.

```
mutate(df,meanage = mean(age))
```

```
##
     id gender age meanage
## 1
         MALE
               70
                      67.6
     1
## 2
                      67.6
     2
         MALE
               76
## 3 3 FEMALE
                      67.6
               60
                      67.6
## 4
     4
         MALE
               64
## 5 5 FEMALE
                      67.6
```

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

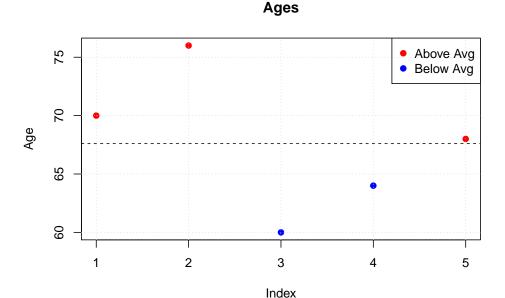

ID	GENDER	AGE	MEANWT
1	MALE	70	67.6
2	MALE	76	67.6
3	FEMALE	60	67.6
4	MALE	64	67.6
5	FEMALE	68	67.6

Next we will create a new column designed to tell us if a given observation has an age that is greater than or equal to the average age. Specifically, create a variable called **old_young** and assign a value of "Y" if the observed age for that row is above the mean age and a value of "N" if it is not.

```
mutate(df,old_young=ifelse(df$age>=mean(df$age),"Y","N"))
```

```
##
     id gender age old_young
## 1 1
         MALE 70
## 2
     2
                          Y
         MALE
               76
## 3 3 FEMALE
               60
                          N
## 4 4
         MALE
               64
                          N
## 5 5 FEMALE
                          Y
               68
```

One way we could use something like this is in making a plot where the observations exhibiting an age value above the mean are plotted in a certain color and those below the mean are in another color.

3.3.3 arrange()

Use arrange for sorting the data frame by one or more columns. When using the basic data frame structure from R we had to use the **order()** function to help us generate a vector that has the row numbers of the data frame that correpsond to the desired order of display (lowest to highest, etc).

Let's sort the data frame **dff** by age from oldest to youngest. First we'll use the older approach. While this will work, it is not exactly very intuitive.

```
df[rev(order(df$age)),]
```

```
##
     id gender age
## 2
      2
          MALE
                 76
      1
          MALE
                 70
## 5
      5 FEMALE
                 68
## 4
                 64
      4
          MALE
## 3
      3 FEMALE
                 60
```

dplyr makes this process more simple - at least in my opinion

```
arrange(df,desc(age))
```

```
## 1 2 MALE 76
## 2 1 MALE 70
## 3 5 FEMALE 68
```

```
## 4 4 MALE 64
## 5 3 FEMALE 60
```

Next, let's sort **df** by gender (alphabetically) and then by age from olderst to youngest. The rows relating to a gender of **female** are going to be listed first because, alphabetically speaking, the letter "F" comes before the letter "M". Then within those categories we have the ages sorted from oldest to youngest.

```
arrange(df, gender,desc(age))
```

```
##
     id gender age
## 1
     5 FEMALE
               68
## 2
     3 FEMALE
               60
## 3 2
          MALE
               76
               70
## 4
     1
          MALE
## 5
         MALE
```

If we used the older approach it would look like the following. Ugh!

```
df[order(df$gender,-df$age),]
```

```
## id gender age
## 5 5 FEMALE 68
## 3 3 FEMALE 60
## 2 2 MALE 76
## 1 1 MALE 70
## 4 4 MALE 64
```

3.3.4 select()

3 3 FEMALE

The select() functions allows us to select one or more columns from a data frame.

```
# Reorder the columns
select(df,gender,id,age)
##
     gender id age
## 1
      MALE 1
               70
## 2
      MALE 2
               76
## 3 FEMALE
               60
            3
## 4
      MALE
            4
                64
## 5 FEMALE 5
               68
# Select all but the age column
select(df,-age)
##
     id gender
## 1 1
         MALE
## 2 2
         MALE
```

```
## 4 4
         MALE
## 5 5 FEMALE
# Can use the ":" operator to select a range
select(df,id:age)
    id gender age
##
## 1 1 MALE 70
## 2 2
         MALE 76
## 3 3 FEMALE 60
         MALE 64
## 5 5 FEMALE 68
The select() function provides the ability to select by "regular expressions"" or
numeric patterns:
# Select all columns that start with an "a"
select(df,starts_with("a"))
##
     age
## 1 70
## 2 76
## 3 60
## 4 64
## 5 68
names(mtcars)
## [1] "mpg" "cyl" "disp" "hp"
                                    "drat" "wt"
                                                  "qsec" "vs"
                                                                        "gear"
## [11] "carb"
# Get only columns that start with "c"
select(mtcars,starts_with("c"))
##
                       cyl carb
## Mazda RX4
                         6
## Mazda RX4 Wag
                         6
                              4
## Datsun 710
                         4
                              1
## Hornet 4 Drive
                         6
                              1
## Hornet Sportabout
                         8
## Valiant
                         6
                              1
## Duster 360

## Volvo 142E
                               2
```

This example is more realistic in that data frames can have a large number of columns named according to some convention. For example, the measurements on a patient might not be labelled specifically - they might have a common prefix such as "m_" followed by some sequential number (or not).

```
testdf <- expand.grid(m_1=seq(60,70,10),
	age=c(25,32),
	m_2=seq(50,60,10),
	m_3=seq(60,70,10))
```

testdf

```

3.3.5 group_by()

The **group_by()** function let's you organize a data frame by some factor or grouping variable. This a very powerful function that is typically used in conjunction with a function called **summarize**. Here is what it looks like by itself. It's somewhat underwhelming. It does seem to create table of some kind but it doesn't do much else.

df

```
##
     id gender age
## 1
     1
          MALE
                70
## 2
      2
                76
          MALE
## 3
     3 FEMALE
                60
## 4
     4
          MALE
                64
## 5 5 FEMALE
                68
# Hmm. the following doesn't do anything - or so it seems
group_by(df)
```

```
## # A tibble: 5 x 3
##
        id gender
                     age
##
     <int> <fct>
                   <dbl>
## 1
         1 MALE
                      70
## 2
         2 MALE
                      76
## 3
         3 FEMALE
                      60
## 4
         4 MALE
                      64
## 5
         5 FEMALE
                      68
```

So as mentioned, the **group_by** function is usually paired with the **summarize** function. Ah. so what this does is to first group the data frame by the **gender** column and then it **counts** the number of occurrences therein. So this is a form of aggregation.

```
summarize(group_by(df,gender),total=n())
```

```
## # A tibble: 2 x 2
## gender total
## <fct> <int>
## 1 FEMALE 2
## 2 MALE 3
```

3.3. FIRST STEPS

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

GENDER	TOTAL	
FEMALE	2	
MALE	3	

Let's group the data frame by gender and then compute the average age for each group.

summarize(group_by(df,gender),av_age=mean(age))

```
## # A tibble: 2 x 2
## gender av_age
## <fct> <dbl>
## 1 FEMALE 64
## 2 MALE 70
```

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

GENDER	AV_AGE
FEMALE	64
MALE	70

Let's group by gender and then compute the total number of observations in each gender group and then compute the mean age.

summarize(group_by(df,gender),av_age=mean(age),total=n())

```
## # A tibble: 2 x 3
## gender av_age total
## <fct> <dbl> <int>
## 1 FEMALE 64 2
## 2 MALE 70 3
```

Chapter 4

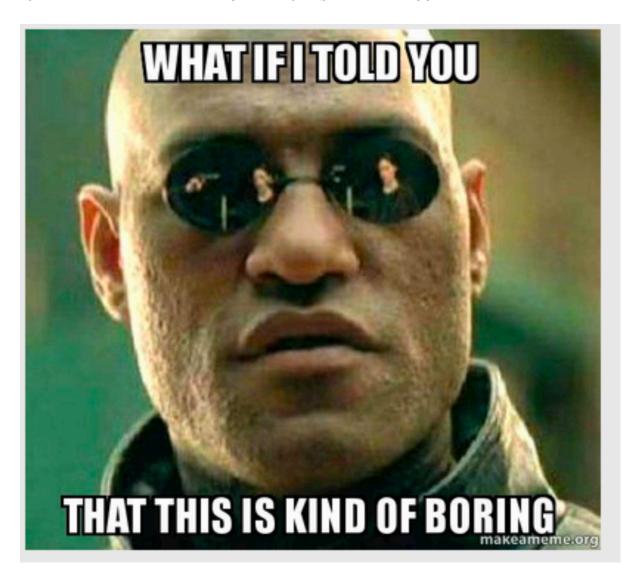

Split Apply Combine

This pattern of using **group_by()** followed by **summarize()** is called **Split Apply Combine**. The idea is that we

- 1) Split up the data frame by gender group
- 2) Then for each group, apply the average function
- 3) Then combine the average results for each group

summarize(group_by(df,gender),av_age=mean(age))

```
## # A tibble: 2 x 2
## gender av_age
## <fct> <dbl>
## 1 FEMALE 64
## 2 MALE 70
```

4.1 What Are Pipes?

Before moving forward let us consider the "pipe" operator that is included with the dplyr - well actually **magrittr** package. This is used to make it possible to "pipe" the results of one command into another command and so on.

The inspiration for this comes from the UNIX/LINUX operating system where pipes are used all the time. So in effect using "pipes" is nothing new in the world of research computation.

```
$ cat /etc/passwd | awk -F ":" '{print $1}' | sort | grep -v "#" | grep -v "_"
daemon
nobody
root
```

Warning: Once you get used to pipes it is hard to go back to not using them.

Let's use the mtcars data frame to illustrate the basics of the piping mechanism as used by dplyr. Here we will select the **mpg** and **am** column from mtcars and view the top 5 rows.

```
head(select(mtcars, mpg, am))
```

```
##
                      mpg
                             am
## Mazda RX4
                     21.0
                            Man
## Mazda RX4 Wag
                     21.0
                           Man
## Datsun 710
                     22.8
                           Man
## Hornet 4 Drive
                     21.4 Auto
## Hornet Sportabout 18.7 Auto
## Valiant
                     18.1 Auto
```

Okay, how would we do this using pipes? Whoa! Note that each command is "it's own thing" independently of the pipe character. So the: - output of mtcars goes into the - input of the **select** function whose output goes into the - input of the **head** function

```
mtcars %>% select(mpg, am) %>% head
```

```
##
                      mpg
                             am
## Mazda RX4
                      21.0
                            Man
## Mazda RX4 Wag
                      21.0
                            Man
## Datsun 710
                      22.8
                            Man
## Hornet 4 Drive
                     21.4 Auto
## Hornet Sportabout 18.7 Auto
## Valiant
                      18.1 Auto
```

Break this down:

```
mtcars %>% select(mpg, am)
```

```
##
                        mpg
                               am
## Mazda RX4
                       21.0
                             Man
## Mazda RX4 Wag
                       21.0
                             Man
## Datsun 710
                       22.8 Man
## Hornet 4 Drive
                       21.4 Auto
## Hornet Sportabout
                       18.7 Auto
## Valiant
                       18.1 Auto
## Duster 360
                       14.3 Auto
## Merc 240D
                       24.4 Auto
## Merc 230
                       22.8 Auto
```

```
## Merc 280
                      19.2 Auto
## Merc 280C

## Fiat 128
                      32.4 Man
## Honda Civic
                      30.4 Man
## Toyota Corolla
                      33.9 Man
## Toyota Corona
                      21.5 Auto
## Dodge Challenger
                      15.5 Auto
## AMC Javelin
                      15.2 Auto
## Camaro Z28
                      13.3 Auto
## Pontiac Firebird
                      19.2 Auto
## Fiat X1-9
                      27.3 Man
## Porsche 914-2
                      26.0
                            Man
## Lotus Europa
                      30.4
                            Man
## Ford Pantera L
                      15.8
                            Man
## Ferrari Dino
                      19.7
                            Man
## Maserati Bora
                      15.0
                            Man
## Volvo 142E
                      21.4 Man
```

The key to understanding how this works is to **read** this from left to right. It bears repeating that each command is "it's own thing" independently of the pipe character. So the:

```
- output of mtcars goes into the
- input of the **select** function whose output goes into the
- input of the **head** function
```

Let's use our new found knowledge to re-imagine our use of the **group_by** and **summarize** functions that we have been using in **composite** form up unitl now.

4.2 Using Pipes To Do Split-Apply-Combine

```
df %>% group_by(gender) %>% summarize(avg=mean(age))

## # A tibble: 2 x 2

## gender avg
## <fct> <dbl>
## 1 FEMALE 64
## 2 MALE 70
```

```
# Same as the following but the pipes don't require you to "commit"
# With the following, you have to know in advance what you want to do
summarize(group_by(df,gender), avg=mean(age))
## # A tibble: 2 x 2
## gender avg
## <fct> <dbl>
## 1 FEMALE 64
## 2 MALE 70
```

This approach allows us to build a "pipeline" containing commands. We don't have to commit to a specific sequence of functions. This enables a free-form type of exploration.

```
df %>%
  group_by(gender) %>%
  summarize(avg=mean(age),total=n())
## # A tibble: 2 x 3
     gender avg total
    <fct> <dbl> <int>
## 1 FEMALE
               64
                      2
## 2 MALE
               70
                      3
What is the median age of all males?
df %>%
 filter(gender == "MALE") %>%
 summarize(med_age=median(age))
```

```
## med_age
## 1 70
```

df

filter

summarize

ID	GENDER	AGE
1	MALE	70
2	MALE	76
3	FEMALE	60
4	MALE	64
5	FEMALE	68

ID	GENDER	AGE
1	MALE	70
2	MALE	76

4.2.1 Saving Results

It should be observed that if you want to save the results of some sequence of commands that you will need to use the "<-" operator. Using the previous example we could the following to save our result.

4.3 An Example

Using the built in mtcars dataframe, do the following:

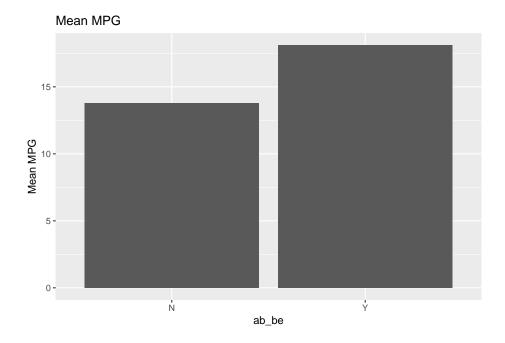

- 1) **filter** for records where the wt is greater than 3.3 tons.
- 2) Then, using the **mutate** function to create a column called ab_be (Y or N) that indicates whether that observation's mpg is greater (or not) than the average mpg for the filtered set.
- 3) Then present the average mpg for each group.

This is easy using pipes and dplyr verbs.

```
## # A tibble: 2 x 2
## ab_be mean_mpg
## <chr> <dbl>
## 1 N 13.8
## 2 Y 18.1
```

This could be then "piped" into the input of the **ggplot** command to plot a corresponding bar chart. If you don't yet know ggplot then it's okay as this will nudge you in that direction. Both **ggplot** and **dplyr** are part of the **tidyverse** which means that the two packages "talk" to each other well.

```
mtcars %>% filter(wt > 3.3) %>%
    mutate(ab_be=ifelse(mpg > mean(mpg),"Y","N") ) %>%
    group_by(ab_be) %>% summarize(mean_mpg=mean(mpg)) %>%
    ggplot(aes(x=ab_be,y=mean_mpg)) +
    geom_bar(stat="identity") +
    ggtitle("Mean MPG") + labs(x = "ab_be", y = "Mean MPG")
```

4.4 Working With Flowers

Let's work with the built in **iris** data frame to explore the world of flowers. This is famous (Fisher's or Anderson's) **iris** data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.

I'll use dyplr idioms here as opposed to the typical Base R approach which might involve use of composite functions. First, load up the iris data

data(iris)

4.4.1 Structure of The Data frame

It's always helpful to look at what types of data you have in a data frame. As you already known, base R has a function called **str** which is useful. The tidyverse equivalent is **glimpse** although the two commands basically provide the same types of information. Personally, I still prefer the "old" **str** function if only because I've been using it for so long.

str(iris)

'data.frame': 150 obs. of 5 variables:

```
##
    $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
    $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
##
   $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
   $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
                  : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 .
   $ Species
glimpse(iris)
## Observations: 150
## Variables: 5
## $ Sepal.Length <dbl> 5.1, 4.9, 4.7, 4.6, 5.0, 5.4, 4.6, 5.0, 4.4, 4.9,...
## $ Sepal.Width <dbl> 3.5, 3.0, 3.2, 3.1, 3.6, 3.9, 3.4, 3.4, 2.9, 3.1,...
## $ Petal.Length <dbl> 1.4, 1.4, 1.3, 1.5, 1.4, 1.7, 1.4, 1.5, 1.4, 1.5,...
## $ Petal.Width <dbl> 0.2, 0.2, 0.2, 0.2, 0.2, 0.4, 0.3, 0.2, 0.2, 0.1,...
## $ Species
                  <fct> setosa, setosa, setosa, setosa, setosa, setosa, s...
```

4.4.2 More Practice

1) Get all the rows where the Species is "setosa" Sepal. Length is >4.7 but <5.0. Use the pipes feature to help you with this.

```
iris %>%
  filter(Sepal.Length > 4.7 & Sepal.Length < 5.0 & Species=="setosa")
##
     Sepal.Length Sepal.Width Petal.Length Petal.Width Species
## 1
              4.9
                          3.0
                                        1.4
                                                    0.2 setosa
## 2
              4.9
                          3.1
                                        1.5
                                                    0.1 setosa
## 3
              4.8
                          3.4
                                        1.6
                                                    0.2 setosa
## 4
              4.8
                          3.0
                                        1.4
                                                    0.1 setosa
## 5
                          3.4
                                                    0.2 setosa
              4.8
                                        1.9
## 6
              4.8
                          3.1
                                        1.6
                                                    0.2 setosa
## 7
                                                    0.2 setosa
              4.9
                          3.1
                                        1.5
## 8
              4.9
                          3.6
                                        1.4
                                                    0.1 setosa
## 9
              4.8
                          3.0
                                        1.4
                                                    0.3 setosa
```

2) Select out only the columns relating Sepal measurements. List only the top five rows:

```
iris %>% select(c(Sepal.Length,Sepal.Width)) %>% head(5)
```

```
Sepal.Length Sepal.Width
##
## 1
               5.1
                            3.5
## 2
               4.9
                            3.0
## 3
               4.7
                            3.2
## 4
               4.6
                            3.1
## 5
               5.0
                            3.6
```

```
# Or use a helper function to process strings
iris %>% select(starts_with("Sepal")) %>% head(5)
##
     Sepal.Length Sepal.Width
## 1
               5.1
                            3.5
## 2
               4.9
                            3.0
## 3
               4.7
                            3.2
## 4
               4.6
                            3.1
## 5
               5.0
                            3.6
# Or if you know which column numbers you want
iris %>% select(c(1:2)) %>% head(5)
##
     Sepal.Length Sepal.Width
## 1
               5.1
                            3.5
## 2
               4.9
                            3.0
## 3
               4.7
                            3.2
## 4
               4.6
                            3.1
## 5
               5.0
                            3.6
  3) Sort the data frame by Sepal. Width such that the row with the largest
     Sepal.Width is listed first. Print only the first 5 rows
iris %>% arrange(desc(Sepal.Width)) %>% head(5)
##
     Sepal.Length Sepal.Width Petal.Length Petal.Width Species
## 1
               5.7
                            4.4
                                         1.5
                                                      0.4 setosa
## 2
              5.5
                            4.2
                                                      0.2 setosa
                                         1.4
## 3
               5.2
                            4.1
                                         1.5
                                                      0.1
                                                           setosa
## 4
               5.8
                                                      0.2 setosa
                            4.0
                                         1.2
## 5
               5.4
                            3.9
                                         1.7
                                                      0.4
                                                           setosa
  4) How many observations are there for each Species group?
iris %>% group_by(Species) %>% count()
## # A tibble: 3 x 2
## # Groups:
                Species [3]
##
     Species
                     n
##
     <fct>
                 <int>
## 1 setosa
                    50
## 2 versicolor
                    50
## 3 virginica
                    50
# Or
iris %>% group_by(Species) %>% summarize(total=n())
```

```
## # A tibble: 3 x 2
## Species total
## <fct> <int>
## 1 setosa 50
## 2 versicolor 50
## 3 virginica 50
```

5) Select all columns that do NOT relate to Length. Limit output to 5 rows

```
iris %>% select(-ends_with("Length")) %>% head()
```

```
Sepal.Width Petal.Width Species
                         0.2 setosa
## 1
             3.5
## 2
             3.0
                         0.2
                              setosa
                         0.2 setosa
## 3
             3.2
## 4
             3.1
                         0.2
                               setosa
## 5
             3.6
                         0.2 setosa
## 6
             3.9
                         0.4
                              setosa
```

6) Select all columns that do NOT relate to Length or Species. Limit output to 5 rows

```
iris %>% select(-c(ends_with("Length"), "Species")) %>% head()
```

```
##
     Sepal.Width Petal.Width
## 1
              3.5
                          0.2
## 2
              3.0
                          0.2
## 3
              3.2
                          0.2
## 4
                          0.2
              3.1
## 5
              3.6
                          0.2
## 6
              3.9
                          0.4
# Or
iris %>% select(-ends_with("Length")) %>% select(-"Species") %>% head()
```

```
##
     Sepal.Width Petal.Width
## 1
              3.5
                            0.2
## 2
              3.0
                            0.2
## 3
              3.2
                            0.2
## 4
              3.1
                            0.2
## 5
              3.6
                            0.2
## 6
              3.9
                            0.4
```

7) Select all columns that do NOT relate to Length or Species. But only for observations where Sepal.Width is > 3.9. There are multiples way to attack this problem.

```
iris %>% filter(Sepal.Width > 3.9) %>%
select(-ends_with("Length")) %>%
```

```
select(-"Species")
##
     Sepal.Width Petal.Width
## 1
             4.0
                          0.2
## 2
             4.4
                          0.4
## 3
             4.1
                          0.1
## 4
             4.2
                          0.2
# Or
iris %>% select(-ends_with("Length")) %>%
  select(-"Species") %>%
 filter(Sepal.Width > 3.9)
##
     Sepal.Width Petal.Width
## 1
             4.0
## 2
             4.4
                          0.4
## 3
             4.1
                          0.1
## 4
             4.2
                          0.2
  8) Determine the mean, standard deviation, max, and min for Sepal.Length
iris %>% summarize(mean=mean(Sepal.Length),
                    sd=sd(Sepal.Length),
                    max=max(Sepal.Length),
                    min=min(Sepal.Length))
##
         mean
                      sd max min
## 1 5.843333 0.8280661 7.9 4.3
  9) For each Species type, determine the mean, standard deviation, max, and
     min for Sepal.Length
iris %>% group_by(Species) %>% summarize(mean=mean(Sepal.Length),
                                           sd=sd(Sepal.Length),
                                           max=max(Sepal.Length),
                                           min=min(Sepal.Length))
## # A tibble: 3 x 5
     Species
                          sd
                               max
                                      min
##
     <fct>
                <dbl> <dbl> <dbl> <dbl> <
                 5.01 0.352
## 1 setosa
                               5.8
                                      4.3
## 2 versicolor 5.94 0.516
                               7
                                      4.9
## 3 virginica
                 6.59 0.636
                               7.9
                                      4.9
```

Chapter 5

Your Turn

Now it's time for you to try some exercises on your own. The **ggplot2** package (which is part of the larger **tidyverse** comes with some data sets one of which is called **msleep**. It's easy to load into your workspace:

data(msleep)

This data set is

an updated and expanded version of the mammals sleep dataset. Updated sleep times and weights were taken from V. M. Savage and G. B. West. A quantitative, theoretical framework for understanding mammalian sleep. Proceedings of the National Academy of Sciences, 104 (3):1051-1056, 2007

COLUMN NAME DESCRIPTION

name	common name
genus	taxonomic rank
vore	carnivore, omnivore or herbivore?
order	taxonomic rank
conservation	the conservation status of the mammal
sleep_total	total amount of sleep, in hours
sleep_rem	rem sleep, in hours
sleep_cycle	length of sleep cycle, in hours
awake	amount of time spent awake, in hours
brainwt	brain weight in kilograms
bodywt	body weight in kilograms

You can always get the names of the columns in a data frame using ${f str}$ or ${f names}$

```
names(msleep)
    [1] "name"
                       "genus"
                                     "vore"
                                                    "order"
    [5] "conservation" "sleep_total"
                                                    "sleep_cycle"
                                     "sleep_rem"
    [9] "awake"
                      "brainwt"
                                     "bodywt"
str(msleep)
## Classes 'tbl_df', 'tbl' and 'data.frame':
                                               83 obs. of 11 variables:
                        "Cheetah" "Owl monkey" "Mountain beaver" "Greater short-tailed
## $ name

```

Not only is this a new data frame for you it also has the added challenge of containing some missing values - those pesky "NAs". In the older approach we used the function **complete.cases** to help us figure out which rows had at least one missin value. We could still use that here although the **dplyr** world has a function called **drop_na()** which could be used but itself or as part of a pipeline.

Here are some questions I want you to answer. Note that the answers are provided so you can check your work. However, the code used to generate the answer is not visible. There is typically more than one way to answer the question.

5.0.0.1 What is the average total sleep time for Omnivores?

```
## # A tibble: 1 x 1
## mean
## <dbl>
## 1 10.9
## # A tibble: 1 x 2
## vore mean
## <chr> <dbl>
## 1 omni 10.9
```

5.0.0.2 Group the msleep data frame by taxanomic order and then summarize the mean sleep total for each group. Make sure the resulting table is arranged in descending order of the average - from highest sleep_total average to the lowest

```
## # A tibble: 19 x 2
##
      order
                         avg
##
      <chr>
                       <dbl>
   1 Chiroptera
                       19.8
##
    2 Didelphimorphia 18.7
    3 Cingulata
                       17.8
    4 Afrosoricida
                       15.6
##
    5 Pilosa
##
                       14.4
    6 Rodentia
                       12.5
    7 Diprotodontia
                      12.4
    8 Soricomorpha
                       11.1
   9 Primates
                       10.5
## 10 Erinaceomorpha
                      10.2
## 11 Carnivora
                       10.1
```

```
## 12 Scandentia
                       8.9
## 13 Monotremata
                       8.6
## 14 Lagomorpha
                       8.4
## 15 Hyracoidea
                       5.67
## 16 Artiodactyla
                       4.52
## 17 Cetacea
                       4.5
## 18 Proboscidea
                       3.6
## 19 Perissodactyla
                       3.47
```

5.0.0.3 What is the average total sleep time for all vore types?

```
## # A tibble: 5 x 2
##
     vore
              mean
##
     <chr>>
             <dbl>
## 1 carni
             10.4
## 2 herbi
              9.51
## 3 insecti 14.9
## 4 omni
             10.9
## 5 <NA>
             10.2
```

5.0.0.4 Omitting any rows that contain missing values, what is the average total sleep time for all vore types? Remember that you will need to use the drop_na function to help you.

```
## # A tibble: 4 x 2
## vore mean
## <chr> <dbl>
## 1 carni 13.3
## 2 herbi 9.52
## 3 insecti 14.0
## 4 omni 12.2
```

5.0.0.5 Remove all rows that contain a missing value and save the result into a new data table called msleep_na. How many rows does msleep_na contain?

```
## [1] 20
```

5.0.0.6 Using msleep_na, find the average braintwt for all vores by order. Note that the group_by() function can take multiple arguments.

```
## # A tibble: 12 x 3
```

##	# (Groups: order	[10]	
##		order	vore	mean
##		<chr></chr>	<chr></chr>	<dbl></dbl>
##	1	Artiodactyla	herbi	0.423
##	2	Artiodactyla	omni	0.18
##	3	Carnivora	carni	0.0478
##	4	Chiroptera	${\tt insecti}$	0.000300
##	5	Cingulata	carni	0.0108
##	6	Didelphimorphia	omni	0.0063
##	7	Erinaceomorpha	omni	0.0035
##	8	Lagomorpha	herbi	0.0121
##	9	Perissodactyla	herbi	0.412
##	10	Rodentia	herbi	0.0032
##	11	Soricomorpha	${\tt insecti}$	0.00120
##	12	Soricomorpha	omni	0.000215

Chapter 6

Taking It To The Next Level

Here we look at some data obtained from the City of Chicago Open Data Portal https://data.cityofchicago.org/. This is data that represents phone calls to the police during the year of 2012. Just pick a folder on your hard drive and download the data.

```
url <- "http://steviep42.bitbucket.org/YOUTUBE.DIR/chi_crimes.csv"
download.file(url,"chi_crimes.csv")</pre>
```
